... a term which in-

of maxillipeds; the mandibles, the first jaws and the seventh pair of legs of insects. The thoracic limbs are important for locomotion; the abdominal limbs maintain a continuous flow of water to the gills and to transport eggs. Finally, the limbs of the last abdominal segments.

Since its DNA does not age, this crustacean could theoretically live indefinitely due to the strain it undergoes during one of the carapace changes and the probability of this phase of its growth.

The heart is located at the back of the thorax behind the gastric region and is colored blue-purple (blue-purple respiratory pigment similar to haemoglobin). The high content of haemoglobin gives the lobster its characteristic purple coloration, but this is only maintained when the lobster remains in the depths. The purple color fades.
